PCs - Platelet Concentrates

PIT - Pathogen Inactivation Technology

PRT - Pathogen Reduction Technology

PSL - Platelet Storage Lesion

LFQ - Label-Free Quantification

UV - Ultraviolet

CCI - Corrected count increment

1D-SDS-PAGE - One dimensional - sodium dodecyl sulphate - polyacrylamide gel electrophoresis

LC-MS/MS - Liquid chromatography - tandem mass spectrometry

DE - Differentially Expressed

vWF-R – von Willebrand Factor Receptor

**ABSTRACT**

Platelet concentrates (PCs) represent a blood transfusion product with a major concern for safety as their storage temperature (20-24°C) allows bacterial growth, and their maximum storage time period (less than a week) precludes complete microbiological testing. Pathogen inactivation technologies (PITs) provide an additional layer of safety to the blood transfusion products from known and unknown pathogens (such as bacteria, viruses and parasites). In this context, PITs (such as Mirasol Pathogen Reduction Technology -PRT-) have been developed and are implemented in many countries. However, several studies have shown *in vitro* that Mirasol PRT induces a certain level of platelet shape change, hyperactivation, basal degranulation and increased oxidative damage during storage. It has been suggested that Mirasol PRT might accelerate what has been described as the platelet storage lesion (PSL), but supportive molecular signatures have not been obtained. We aimed at dissecting the influence of both variables, *i.e.* Mirasol PRT and storage time, at the proteome level. We present comprehensive proteomics data analysis of Control PCs and PCs treated with Mirasol PRT at storage days 1, 2, 6 and 8. Our workflow was set to perform proteomics analysis using a gel-free and label-free quantification (LFQ) approach. Semi-quantification was based on LFQ signal intensities of identified proteins using MaxQuant/Perseus software platform. Data are available via ProteomeXchange with identifier PXD008119. We identified marginal differences between Mirasol PRT and control PCs during storage. However, those significant changes at the proteome level were specifically related to the functional aspects previously described to affect platelets upon Mirasol PRT, and in addition, the effect of Mirasol PRT on the platelet proteome appeared not to be exclusively due to an accelerated or enhanced PSL. In summary, semi-quantitative proteomics allows to discern between proteome changes due to Mirasol PRT or PSL, and proves to be a methodology suitable to phenotype platelets in an unbiased manner, in various physiological contexts.

## INTRODUCTION

Transfusion transmitted infections (TTIs) pose a threat in transfusion practice as there are still infections for which routine tests are not available or cannot be performed at each hospital or blood bank, *i.e.* **Chikungunya** virus, *Dengue virus*, *Human Parvovirus B19*, *Toxoplasma* or *Babesia* [1, 2]. Although bacterial screening of blood products is mandatory in many countries, studies have shown that bacterial infections represent a major threat to transfusion products (especially platelets) compared to viral infections [1-4]. Since platelet concentrates (PCs) are stored at room temperature (20-24°C) approximately for 1 week, they are at risk of contamination because this temperature allows the growth of bacteria that might be present and the storage period precludes complete microbiological testing. It has been shown that bacteria from the skin flora at the phlebotomy site are present in 70% of the transfusion-related sepsis cases [5, 6]. Therefore, in order to minimize the infection risk of transfusion products, Pathogen Inactivation Technologies (PITs) were developed [7, 8].

As of November 2017, Mirasol PRT (Terumo BCT, USA) PCs treatment has been approved and is in routine use in 22 countries (Susanne Marschner, personal communication). It consists of the addition to PCs of riboflavin -a naturally occurring photosensitizer that binds to nucleic acids (DNA or RNA)- followed by UV illumination (265-370 nm), which causes nucleic acid single strand breaks that cannot be repaired in pathogens [4, 9-12]. Mirasol PRT can reduce the pathogen-load including a wide range of viruses and bacteria by 4 to 6-log [13-15]. Additionally, Mirasol PRT prevents **leukocyte** proliferation and cytokine production, counteracting potential risks of alloimmunization [16-20].

The positive aspect of Mirasol PRT is that riboflavin and its metabolic by-products do not need to be removed after UV illumination because they are naturally occurring and FDA-approved [21]. A randomized clinical trial conducted in France demonstrated that transfusion

1  
2  
3 of Mirasol PRT PCs is not associated with adverse reactions in patients compared to Control  
4 PCs, supporting their safety. However, although the post-transfusion platelet corrected count  
5 increment (CCI) values were above the required minimum threshold, they were lower in the  
6  
7 group transfused with Mirasol PRT PCs [22]. Several *in vitro* studies showed that some  
8  
9 quality parameters were unaffected until day 5 of storage in Mirasol PRT PCs compared to  
10  
11 Control PCs [23-27]. Our previous studies showed that Mirasol platelets undergo  
12  
13 spontaneous aggregation in the absence of agonist (hyperactivation), due to basal continuous  
14  
15 platelet degranulation induced by Mirasol PRT, and that this effect was more severe late upon  
16  
17 storage [27]. Additionally, it has been shown that Mirasol PRT enhances GPIb $\alpha$  shedding  
18  
19 and desialylation of platelet surface proteins, affects platelet adhesion and induces shape  
20  
21 changes to platelets late upon storage [28, 29].

39  
40 Various blood components (plasma, platelets, RBCs) have been studied using proteomic  
41  
42 approaches **lately** [31]. Since platelets are anucleated entities containing a proteome of the  
43  
44 order of thousand [31], it is feasible to measure qualitative and (ideally) quantitative changes  
45  
46 in PCs upon storage and/or Mirasol PRT. In this study we have used an unbiased, label-free  
47  
48 quantification (LFQ) proteomics approach that allows the comparison of global trends in the  
49  
50 proteomes of the studied groups. With this technique we aimed at gaining insight on the  
51  
52 effects of Mirasol PRT and storage on the platelet proteome at the qualitative and semi-  
53  
54 quantitative level. This analysis allowed us to relate the limited identified proteomic changes

## METHODS

### *Experimental design*

PCs were produced and stored at Sanquin Dutch Blood Bank according to national standards, meeting the requirements for Mirasol PRT. 105 healthy donors participated after giving informed consent. The study was approved by our institute medical ethics committee in accordance with the 1964 Declaration of Helsinki.

Per experiment, and as previously described [27], six buffy coat derived PCs were pooled at day 1 after blood donation and processing, and split back in six equal units. Three of these units were left untreated while the other three were treated with Mirasol PRT (Terumo BCT, Zaventem, Belgium). We collected samples from day 1 PCs before treatment, and from a single Control and a single Mirasol PRT unit at day 2, 6 and 8 of storage. Platelets and supernatants were separated by centrifugation (4000 rpm 5 minutes), and the supernatant fraction was collected after an additional centrifugation step (10000 rpm 1 minute). Platelet pellets and PC supernatants were snap frozen and stored at -80°C. The experiment was replicated several times, and we gathered 3 Control and 4 Mirasol PRT sets, for which different donors were employed. Freshly isolated platelets and plasma were obtained by centrifugation from citrate-anticoagulated blood sampled from three independent donors.

### *Protein extraction and processing for mass spectrometry acquisition*

Platelets were lysed in 8M urea (ThermoFisher Scientific, Waltham, MA, USA) in 100mM TRIS-HCl pH 8 (ThermoFisher Scientific). 5 µg protein were used for further in-solution processing. Disulfide bonds were reduced with 10mM DTT (ThermoFisher Scientific) 60 minutes at 20°C, alkylated with 55mM iodoacetamide (ThermoFisher Scientific) 45 minutes at 20°C. Samples were digested 16 hours at 20°C with MS-grade trypsin (Promega, Fitchburg, WI, USA) in a 1:20 trypsin:protein ratio. Peptides were desalted and concentrated using 3M

*Platelet Proteomics, Storage Time and Mirasol PRT*

Empore-C18 StageTips (Sigma-Aldrich, St. Louis, MO, USA) as described [32] and eluted with 0.5% acetic acid (Sigma-Aldrich), 80% acetonitrile (Biosolve Chimie, Dieuze, France). Sample volume was reduced by SpeedVac and supplemented with 2% acetonitrile, 0.1% TFA (ThermoFisher Scientific) to a final volume of 5  $\mu$ l, of which 3  $\mu$ l were injected for MS acquisition. Peptides were separated by nanoscale C18 reverse phase chromatography coupled on line to an Orbitrap Fusion Tribrid mass spectrometer (ThermoFisher Scientific) via a nanoelectrospray ion source (Nanospray Flex Ion Source, ThermoFisher Scientific), following standard procedures and settings, and acquired with Xcalibur software.

*Proteomics data analysis*

The mass spectrometry data were analysed with MaxQuant software version 1.5.5.1 using default settings and Label Free Quantification (LFQ), searching against the UniProt KB human taxonomy database [33-35]. The output Protein Groups table generated was used for further analysis with Perseus software version 1.5.5.3. A log<sub>2</sub> transformation was applied to all LFQ intensity values. Data was filtered so that at least 1 group had at least 3 valid values. Missing values were imputed using normal distribution. All T-Tests, with multiple testing correction, and Multiple-Sample Tests were performed setting FDR at 5% (Benjamini-Hochberg) and  $S_0 = 0$  [36]. Soft clustering of proteins was done using K-means. The mass spectrometry proteomics data have been deposited to the ProteomeXchange Consortium via the PRIDE partner repository with the dataset identifier PXD008119 [37-39]. GO-Term searches were performed using STRING web-based software platform, version 9.1 (<http://string-db.org/>) [40, 41].

*Flow cytometry-based platelet aggregation assay (FCA)*

Flow cytometry-based platelet aggregation assay was performed as described [42]. The agonists used were phorbol myristate acetate (PMA-100 ng/mL), convulxin (2  $\mu$ g/mL), collagen (10  $\mu$ g/mL) and ristocetin (1.5 mg/mL). Aggregation was measured by flow

1  
2  
3 cytometry (LSRII+HTS, BD Biosciences, San José, CA, USA) through a time-series per  
4  
5 agonist, and data was analysed with FlowJo software (Version 9.2, Tree Star Inc., Ashland,  
6  
7 OR, USA). The area under the curve (AUC) of each reaction was used as aggregation  
8  
9 capacity variable. Student's T-test analyses were performed in order to identify significant  
10  
11 differences.

#### 12 13 *Western blot analysis*

14  
15 Platelet lysates (RIPA), or PC supernatants depleted of albumin/IgG (Pierce™ Albumin/IgG  
16  
17 Removal Kit, #89875, ThermoFisher Scientific) were subject to 1D-SDS-PAGE and  
18  
19 immunoblotting was performed. We used as primary antibodies anti-EMILIN1 (ab56936,  
20  
21 Abcam, Cambridge, UK), anti-NID1 (AF2570), anti-NID2 (AF3385) and anti-THBS1  
22  
23 (AF3074) from Bio-Techne (Minneapolis, MN, USA); anti-GP5 (sc-271662), anti-APOH  
24  
25 (sc-515677) and anti-MPL (H300, sc-15403) from Santa Cruz Biotechnology (Dallas, TX,  
26  
27 USA); anti-GAPDH (MAB374, Darmstadt, Merck, Germany); and as secondary antibodies  
28  
29 we used anti-mouse (#31430) and anti-rabbit (#31460) from ThermoFisher Scientific; anti-  
30  
31 goat (A16005, Invitrogen, Carlsbad, CA, USA); or anti-mouse (NA93IV, GE Healthcare,  
32  
33 Little Chalfont, UK) all IgG HRP conjugated. Membranes were developed with  
34  
35 Chemiluminescence (Amersham, Little Chalfont, UK). Gels were stained with Imperial™  
36  
37 Protein Stain #24615 or with Pierce™ Glycoprotein Staining Kit #24562 (ThermoFisher  
38  
39 Scientific).

## RESULTS

Mirasol PRT induces functional changes, *i.e.* hyperactivation and basal degranulation [23, 25, 27, 43]. It has been suggested that Mirasol PRT accelerates the platelet storage lesion (PSL) on PCs. To gain insight into this functional phenomenon, and complementing our previous observations [27], we took advantage of a flow-cytometry based platelet aggregation assay that allows the study of the contribution of single receptors to the early steps of platelet aggregation, depending on the agonist applied, to compare platelet responses between Control and Mirasol PRT PCs (Figure 1) [42]. We used as agonists PMA (activating  $\alpha 2\beta 3$ ), ristocetin (activating vWF-Receptor), convulxin (activating GP6) and collagen (activating both GP6 and  $\alpha 2\beta 1$ ), and freshly isolated platelets as a reference. As known [44-46], Control PCs platelets lose aggregation capacity upon storage, and our assay shows that it is  $\alpha 2\beta 1$ - and, to a lesser extent, vWF-R- and GP6-mediated responses that are affected. Mirasol PRT platelets displayed more severely reduced vWF-R- and GP6-mediated responses, while the  $\alpha 2\beta 1$ -mediated response was equally affected compared to Control PC platelets.  $\alpha 2\beta 3$ -mediated responses are generally preserved in both groups. This data suggests that the functional capacity loss observed in Control and Mirasol PRT PCs upon storage is characteristic, supporting the notion that the processes affected by either Mirasol PRT or PSL are distinct.

### *A proteomic approach to unravel differences induced by Mirasol PRT and/or storage*

We questioned ourselves whether we could distinguish between Mirasol PRT and PSL-related defects in an unbiased manner and therefore, we aimed at analysing alterations in the platelet proteome of Mirasol PRT and Control PCs during storage (Figure 2A-D). Prior mass spectrometry acquisition, platelet protein extracts prepared from fresh platelets, day 1 PCs before treatment, and Control or Mirasol PRT replicate PCs at different time points during storage (*i.e.* day 2, 6 and 8) were subject to in-solution trypsin digestion (as opposed to in-gel

1  
2  
3 digestion), in order to reduce the processing steps of the sample, while still gaining deep  
4  
5 protein coverage.

6  
7 Identification and quantitation of proteins was done with label-free quantification (LFQ)  
8  
9 using MaxQuant and Perseus software platforms (PRIDE accession number PXD008119).  
10  
11 We identified 3445 protein groups across samples and 40537 corresponding peptide  
12  
13 sequences. We next filtered identified proteins from 3445 to 2505 by removing potential  
14  
15 contaminants (with the exception of THBS1 and TPM2, which are present in platelets), only  
16  
17 identified by site, reverse sequences and duplicate entries (*i.e.* protein groups). Principal  
18  
19 Component Analysis (PCA) of all samples analysed shows three populations: Control PCs  
20  
21 together with fresh platelets, Mirasol PRT, and, as an isolated population, day 1 PCs (Figure  
22  
23 2E).  
24  
25

#### 26 27 *Comparison of the proteome of Control and Mirasol PRT PCs through storage*

28  
29

30 We compared the Control and Mirasol PRT PCs proteomes at day 2, 6 and 8 of storage, in  
31  
32 order to identify potential proteomic differences (Table S1). Importantly, PCA and Pearson  
33  
34 correlation analysis of replicates within the Control and Mirasol PRT groups showed that  
35  
36 Control samples correlated strongly with each other, while Mirasol PRT samples displayed  
37  
38 more heterogeneity, *i.e.* some of the Mirasol PRT samples cluster together with Control  
39  
40 samples, and do not correlate strongly within the Mirasol PRT group (Figure 3A-B). This  
41  
42 suggests that the effect of Mirasol PRT on the PC proteome ranges, most probably on a  
43  
44 donor-dependent manner.  
45  
46

47  
48 Unsupervised hierarchical clustering of Control and Mirasol PRT PCs averaged per time  
49  
50 point generated distinct clusters, separating Mirasol PRT from Control PCs (Figure 3C). The  
51  
52 first cluster included Control PCs at day 2, the second included Control PCs at days 6 and 8,  
53  
54 the third included Mirasol PRT PCs at day 2 and the fourth comprised Mirasol PRT PCs at  
55  
56

*Platelet Proteomics, Storage Time and Mirasol PRT*

1  
2  
3 days 6 and 8. Both Control and Mirasol PRT PCs samples at day 2 separated from the rest.  
4  
5 The clustering of Control or Mirasol PRT PCs at days 6 and 8 suggests respective common  
6  
7 proteomic changes late during storage. However, based on Pearson index, day 6-8 Control or  
8  
9 Mirasol PRT PCs do not correlate strongly amongst each other, suggesting distinct changes  
10  
11 due to Mirasol PRT (Figure 3D).  
12

*Proteome alterations due to Mirasol PRT are minimal but increase with storage time*

13  
14  
15  
16  
17 We performed T-tests in order to identify differences at the proteome level amongst  
18  
19 treatments at each day of storage, however, we could not identify any (Table S1). However,  
20  
21 multiple-sample test analysis led to the identification of a total of 20 proteins that were  
22  
23 significantly differentially expressed (DE) between Mirasol PRT and Control PC samples  
24  
25 (Table 1 and Table S1). Unsupervised hierarchical clustering was performed and is shown in  
26  
27 Figure 4A. Interestingly, the majority of downregulated DE proteins are contained in  $\alpha$ -  
28  
29 granules [47] and are related to platelet functions such as adhesion, activation and  
30  
31 degranulation by GO-Term search (Figure 4, Table S2 and Figure S1). Furthermore,  
32  
33 upregulated DE proteins locate mainly in mitochondria and plasma membrane. This data  
34  
35 supports the notion that Mirasol PRT induces basal platelet degranulation (as downregulated  
36  
37 proteins, which locate to  $\alpha$ -granules, are probably secreted). Upregulated (or enriched  
38  
39 proteins that are not secreted thereof) locate to mitochondria and membrane domains,  
40  
41 corroborating previous findings that Mirasol PRT does not alter mitochondria integrity in PCs  
42  
43 [23, 27].  
44  
45  
46

47  
48 We analysed by Western blotting (Figure 5A) the expression of some of the DE proteins and  
49  
50 unaltered ones in platelet lysates. We confirmed downregulation of EMILIN1, GP5, NID1,  
51  
52 NID2 and THBS1, some of them being visibly reduced by day 8, others affected already by  
53  
54 day 6. We confirmed overexpression of APOH, while MPL and GAPDH were barely  
55  
56

1  
2  
3 affected in Mirasol PRT compared to Control platelets. Coomassie staining shows that the  
4  
5 protein concentration is homogeneous. Curiously, GP5 is also downregulated in Control PCs,  
6  
7 however, the downregulation is more severe in Mirasol PRT. This correlates with the  
8  
9 dynamics of vWF-R-mediated responses, which are affected in both groups, although more  
10  
11 severely in Mirasol PRT platelets, upon storage (Figure 1) [29].  
12  
13

14  
15 In order to prove that downregulation of proteins in Mirasol PRT platelet proteomes is due to  
16  
17 degranulation, we analysed their expression in the supernatants of respective samples (Figure  
18  
19 5B). Data shows presence of EMILIN1 in Mirasol PRT supernatants, while it is undetectable  
20  
21 in Control PCs and fresh plasma sample. Regarding NID1 and NID2, they are barely  
22  
23 detectable in fresh plasma samples, and they are detectable in Control supernatants, however  
24  
25 the amount is higher -and earlier during storage- in Mirasol PRT supernatants in the case of  
26  
27 NID2. Interestingly, the amount of protease-cleaved NID1 (arrowheads) is higher in Mirasol  
28  
29 PRT supernatants, suggesting active proteolysis, occurring at a higher extent than in Control  
30  
31 PCs. Coomassie staining shows that the amount of protein present in supernatants is higher at  
32  
33 day 8 in both Control and Mirasol PRT samples, and arrowheads display bands altered on  
34  
35 sample protein patterns. Interestingly, Glycoprotein staining reveals extra bands in Mirasol  
36  
37 PRT supernatants early upon storage, bands that are not detectable in fresh plasma or Control  
38  
39 supernatants (weak bands are seen only at day 8). This supports the notions that there is  
40  
41 active Mirasol PRT-dependent protein release from platelets, and that there might be active  
42  
43 proteolysis, as consequence of degranulation-dependent release of platelet proteases.  
44  
45  
46

#### *Comparison of the proteome of fresh platelets and Control PCs through storage*

47  
48  
49 The recommended shelf life of PCs, ranging from 3 to 7 days, is still a matter of discernment  
50  
51 amongst different countries, where transfusion policies differ due to both the risk of bacterial  
52  
53 contamination and the acknowledged platelet storage lesion (PSL) [48, 49]. PSL is associated  
54  
55

*Platelet Proteomics, Storage Time and Mirasol PRT*

1  
2  
3 with reduced *in vivo* platelet recovery, survival and haemostatic activity after transfusion  
4 [50]. To identify protein changes due to storage, the proteome of freshly isolated platelets  
5 was compared with the proteome of platelets from PCs at storage days 1, 2, 6 and 8 (Figure 2  
6 and Table S3).  
7  
8  
9

10  
11  
12 PCA and Pearson correlation analysis showed that in general, fresh (D0) platelet proteome  
13 differs from stored Control PCs (Figure 6A-B), however, day 1 PCs samples separate clearly  
14 from further stored or fresh platelet samples. Unsupervised hierarchical clustering generated  
15 distinct clusters (Figure 6C) and showed a unique proteome from each sample. Consequently,  
16 these samples did not correlate with each other, although fresh platelets tend to pair with day  
17 2, and day 6 with day 8, leaving day 1 PCs platelets isolated (Figure 6D). Our explanation for  
18 this is that day 1 PC platelet proteomes might be skewed due to a percentage of old, hyper-  
19 reactive or apoptotic platelets that are “stressed and visible” due to recent sampling and  
20 processing.  
21  
22  
23  
24  
25  
26  
27  
28  
29  
30

31  
32 None of the identified proteins were significantly DE taking either fresh or day 1 stored  
33 platelets as reference (with isolated exceptions) and we also did not identify differentially  
34 expressed proteins employing multiple-sample test analysis (Table S3).  
35  
36  
37  
38

39  
40 However, we wanted to evaluate potential protein level dynamics influenced by storage that  
41 could explain the functional differences observed between Mirasol PRT and Control PCs or  
42 those dependent on storage. Therefore, we performed cluster analysis of protein expression  
43 dynamics during platelet storage (days 2, 6 and 8), (Figure S2 and Table S4). Particularly  
44 interesting were clusters 4, 6, 8 and 9, in which respective protein groups undergo  
45 downregulation at the beginning or end of storage (being clusters 1, 2 and 7 their mirror  
46 responsive clusters respectively). GO-Term analysis from clusters 1-9 is provided in Table  
47 S4. In general, there are a number of proteins in these clusters that participate in vesicular  
48  
49  
50  
51  
52  
53  
54  
55  
56

1  
2  
3 transport and metabolic pathways, which do not correlate to the GO-Term enrichment  
4  
5 derived from the DE proteins induced by Mirasol PRT. In addition, the expression tendencies  
6  
7 are not shared when comparing the effects of Mirasol PRT or storage, *i.e.* not all  
8  
9 downregulated proteins due to Mirasol PRT are downregulated in Control platelets through  
10  
11 storage.  
12

13  
14 Summarizing, storage does not critically affect the platelet proteome, although there were  
15  
16 protein expression dynamics identified through cluster analysis, which supported the lowered  
17  
18 aggregation capacity displayed late during storage and the partial overlap with Mirasol PRT-  
19  
20 induced proteomic changes. Furthermore, our data show that Mirasol PRT generates minimal  
21  
22 alterations at the proteome level, however, those alterations are linked to the functional  
23  
24 changes that have been observed (*i.e.* basal degranulation) and are more severe upon storage  
25  
26 [27].

## DISCUSSION

Several *in vitro* studies have reported the effect of Mirasol PRT on platelet quality, and while the conclusions on the extent of the impact of Mirasol PRT on PCs differs among studies, it is generally acknowledged that Mirasol PRT, and other PITs, do exert an effect on the treated transfusion product [23, 25, 27, 51-54]. Here we applied state-of-the-art mass spectrometry technology to analyse the effect of Mirasol PRT on the platelet proteome. We have identified 20 DE proteins (out of ~ 2500) upon Mirasol PRT in comparison to Control PCs, suggesting that very few proteins are affected. Our results are in agreement with previous studies **showing** that Mirasol PRT affected only a handful of proteins (**mainly** related to the cytoskeleton and metabolism), despite the differences in methods and data analyses employed, *i.e.* in-solution digestion and label-free quantification (LFQ) vs in-gel digestion [24, 55]. Such knowledge might contribute to the development of alternatives to improve PIT PCs quality parameters and maximize the efficacy of a safe transfusion product. For example, a study reported that p38MAPK was hyper-phosphorylated in Mirasol PRT platelets, and that adding a p38MAPK-specific inhibitor before treatment, resulted not only in decreased phosphorylation of its substrates such as VASP, AKT and HSP27, but also on improved platelet function and survival [56, 57].

Interestingly, none of these 20 proteins identified in the present study appear in earlier proteomic studies in Mirasol treated platelets, with the exception of THBS1 [24, 28, 55]. Further analysis of the MS data revealed that most of these DE proteins are components of  $\alpha$ -granules of platelets [47, 58], which support our previous findings that Mirasol PRT leads to platelet hyperactivation due to basal degranulation [27]. Platelet degranulation is accompanied by the release of proteases, which result in shedding of receptors such as GPIIb/IIIa and platelet desialylation, as reported [29]. Identified platelet proteases ADAM10 and MMP1

1  
2  
3 (Table S1), get reduced by Mirasol PRT -although not significantly-. Platelet released  
4 proteases and those present in plasma, might account for the enhanced cleavage of  
5 susceptible proteins, such as NID1 [59]. It has been described that NID1, a component of  
6 basal membranes involved in cell-matrix interactions, binds to fibrin and fibrinogen [60].  
7 However, it is not known whether the increased levels of NID1 (and general released/secreted  
8 platelet cargo) or proteolytic products may alter haemostasis or influence tissue regeneration  
9 [59]. Glycoprotein and Coomassie staining of PCs supernatants revealed different patterns  
10 between Mirasol PRT compared to fresh plasma, suggesting active modification of plasma  
11 protein components. However, how these modifications might affect transfusion product  
12 performance is unknown. This aspect also adds to the current opinion that Platelet Additive  
13 Solution (PAS) might be preferred over the use of plasma for PC storage [61]. It is important  
14 to acknowledge that downregulation of proteins such as MMRN1 or EMILIN1 in the platelet  
15 proteome, is not necessarily caused by the same biological process (*i.e.* degranulation).  
16 Control PCs experience also downregulation of MMRN1 and EMILIN1 through storage,  
17 based on our Cluster analysis, however, we have evidence that it is not merely due to basal or  
18 active degranulation, but other processes may play a role, such as vesiculation.

37

38 We observed that upon storage, ristocetin-mediated responses were reduced, and this  
39 reduction was more severe on Mirasol PRT PCs. Ristocetin induces platelet agglutination  
40 through the GP1b-IX-V receptor complex; our proteomics data showed downregulation of  
41 GP5 upon Mirasol PRT, and cluster-based analysis shows that GP5 expression dynamics  
42 (cluster 4) display a reduction tendency in Control PCs. GP5 downregulation was observed  
43 by Western blot analysis in Control PCs, downregulation that was more severe on Mirasol  
44 PRT PCs (Figure 5). These data goes along the ristocetin-mediated response reduction in  
45 PCs, which is more severe in Mirasol PRT PCs, and recent in vitro studies that show that

2  
3 Mirasol PRT enhances GPIb $\alpha$  shedding and platelet desialylation [29]. The recently-  
4 completed PREPAREs trial showed minor differences in the percentage of patients with  
5 major bleeding complications after transfusion, comparing Mirasol PRT with Control PCs  
6 [30]. However, it remains to be evaluated whether those minor differences correlate with the  
7 transfusion of older vs younger PCs, i.e. the storage time.  
8  
9  
10  
11  
12

13  
14 When analysing the platelet proteome of Control PCs through storage, we could not identify  
15 DE proteins. However, K-means cluster analysis suggested proteomic dynamic changes  
16 through storage. From the 20 proteins DE upon Mirasol PRT, not all were affected or  
17 changed in the same direction, based on cluster analysis. From the downregulated DE  
18 proteins upon Mirasol PRT, only GP5, MMRN1, EMILIN1, NID2, THBS1 and TSC22D3  
19 belong to clusters with clear expression downregulation upon storage, while NID1, MLEC,  
20 ENDOD1, TMED7 and VAT1 follow opposite kinetics. On the other hand, from the  
21 upregulated DE proteins upon Mirasol PRT, only FH, DECR1 and ALDH4A1 follow the  
22 same pattern upon storage in Control PCs. Therefore, cluster analysis revealed that the  
23 proteome profile of Mirasol PRT and storage lesion overlaps partially, although proteomic  
24 signatures are distinct.

39 Our study has some limitations, as we discarded protein hits with poor peptide coverage, and  
40 protein modifications or fragmentation were not studied. It has been shown that oxidative  
41 damage was induced by Mirasol and Intercept (Amotosalen) treatments on model peptides  
42 [53]. Results from this study revealed that Mirasol PRT generated more oxidation on peptides  
43 and Mirasol and Amotosalen induced different peptide modifications at different sites. In  
44 addition, the identification of low abundant proteins in platelet lysates might be an extra  
45 limitation of the current methodology, and significant differences identified depend on the  
46 stringency of the statistical analysis performed.

54  
55

1  
2  
3 In summary, we have demonstrated that Mirasol PRT impacts few proteins in platelets and  
4 these are mostly related to platelet adhesion, activation and degranulation. However, we did  
5 not find significant DE proteins between fresh and stored platelets and cluster analysis  
6 suggests that PSL and Mirasol PRT have partially overlapping but distinct signatures.

**FIGURE LEGENDS**

**Figure 1. Flow cytometry–based PLT aggregation assay.** Aggregation of PLTs from Control and Mirasol PRT PCs at day 2, day 6, and day 8 of storage upon addition of the agonists PMA, collagen, Convulxin, and Ristocetin over an incubation period of 5 minutes is depicted. Aggregation was measured by flow cytometry as percentage of double-colored events through a time-series course, and the Area Under the Curve (AUC) was calculated. Mean and SEM of three independent experiments are shown. D0 are fresh platelets used as reference. \* $p < 0.05$ , \*\* $p < 0.01$ , \*\*\* $p < 0.001$ . When the asterisk is blue, the comparison was made with D0 fresh reference platelets. When the asterisk is grey, comparison has been made with the day Control platelet samples.

**Figure 2. Schematic overview of the sample preparation and proteomics workflow. (A)** Platelet concentrate (PC) preparation is done using a buffy coat-based differential centrifugation method. 1 PC unit is made of 5 units of donated whole blood (WB). RBCs, red blood cells; PLTs, platelets. **(B)** Experimental setup for Mirasol PRT and Control PC sampling. On each experiment, 6 PCs were pooled together and divided again into 6 units. From these, 3 units were Mirasol PRT treated and the other 3 were left untreated (Control PCs). Samples for platelet function and protein lysate preparation were collected from individual units at day 2, 6 and 8. **(C)** Fresh platelets were isolated by differential centrifugation, and were subsequently used for functional analysis and protein lysate preparation. **(D)** Equal amounts (5  $\mu\text{g}$  protein) from platelet lysate samples were subject to trypsin digestion (in-solution digestion), followed by Orbitrap Fusion™ Tribrid™ MS analysis. Proteins were identified using MaxQuant version 1.5.5.1 (<http://www.maxquant.org>) coupled to Andromeda search engine. Subsequent label-free quantification bioinformatic analysis was performed in Perseus software version 1.5.5.3

(<http://www.perseusframework.org>). **(E)** Principal Component Analysis of all files included in the study. D0 are fresh platelets.

**Figure 3. Proteome comparison Mirasol PRT and Control PCs during storage.** **(A)** Principal Component Analysis of Mirasol PRT and Control PCs at days 2, 6 and 8. **(B)** Matrix representation of Pearson correlation values of the proteome of Mirasol PRT and Control PC platelet lysate replicates through storage. **(C)** Two-way unsupervised hierarchical clustering of the median protein expression values of the proteome of Control and Mirasol PRT platelet lysate samples at day 2, 6 and 8 of storage. **(D)** Matrix representation of Pearson correlation values of the proteomes of each averaged stored Control and Mirasol PRT platelet sample-group against the others.

**Figure 4. Proteins differentially expressed in Mirasol PCs are minimal, and locate to alpha-granules.** **(A)** Two-way unsupervised hierarchical clustering of the normalized expression values of all 20 significant proteins was performed. Control and Mirasol PRT PC sample replicates were clustered. **(B)** Graphical representation of the DE proteins indicating their assigned cellular compartment. Most of the downregulated DE proteins are located to alpha-granules, while most of the upregulated DE proteins are located to mitochondria and plasma membrane.

**Fig. S1**

**SUPPORTING FILES LEGENDS**

**Figure S1: STRING analysis of differentially expressed (DE) proteins after Multiple Sample Test Analysis of Mirasol PRT vs Control PCs.** Protein-protein functional interactions and GO-Term enrichment are depicted for the total of DE proteins, and separately for down- and upregulated DE proteins (Table S4).

**Figure S2. Dynamics of platelet protein changes through storage.** Dynamics of protein changes were analyzed by K-means using Perseus software. Time-course kinetics of significant proteins in 9 different clusters is shown. On the X-axis, time points indicate Day 2, Day 6 and Day 8 of platelet storage while on the Y-axis, the respective expression values of proteins in the cluster are depicted. The black lines represent the average expression of all proteins while coloured lines are the expression (LFQ intensity value) of the clustered proteins. Below, relevant enriched Biological Process GO-Terms are shown. Proteins DE in Mirasol vs Control PCs are also indicated (blue, downregulated and red, upregulated). Other proteins of interest within the cluster are indicated.

**Table S1: Proteomic Analysis of Control vs Mirasol PC Lysates through Storage.**

Indicated are the Average Log<sub>2</sub> LFQ of Control and Mirasol PCs samples at Days 2, 6 and 8 of Storage, Log<sub>2</sub> LFQ fold ratios Mirasol vs Control at different Days, FDR (t test), Multiple Sample test ANOVA significant entries and corresponding FDR, and the individual Log<sub>2</sub> LFQ values of individual Control and Mirasol Samples. LFQ = Label Free Quantification; FDR = false discovery rate; C = Control; M = Mirasol, D = Day.

**Table S2: Gene Ontology (GO) Term (GO-Term) enrichment analysis of significantly differentially expressed (DE) proteins identified after Multiple Sample test comparing Control and Mirasol PRT PCs through storage.** From the 20 significant DE proteins,

1  
2  
3 STRING-based GO-Term enrichment analysis was performed on the total, down-and  
4  
5 upregulated datasets. All identified Terms are depicted, including Biological Process,  
6  
7 Biological Function, Cellular component and KEGG pathway.
